Understanding the impact of military service on veterans and the importance of military service-related Traumatic Brain Injury (TBI) remains a significant challenge. The military, through the Defense and Veterans Affairs (VA) systems, has been working to improve the care and treatment of those with mild, moderate, and severe TBIs.

The military, led by organizations such as the Department of Defense (DoD) and the VA, has taken several steps to improve care for those with TBI. These include the development of cognitive rehabilitation tools, the implementation of standardized mental status assessment tools, and the expansion of care providers to include non-military personnel.

However, challenges remain. The identification of personnel who have TBI is a significant cause of disability outside of military settings, and often these individuals do not receive timely care. This is particularly true for those with mild TBI, as they may not seek medical attention after their injury.

In addition, the military continues to struggle with diagnosing and treating mild TBI, which can manifest in a variety of ways. Mild TBI can be categorized as mild, moderate, or severe and can lead to a wide range of symptoms, including cognitive, emotional, and physical changes.

Given the complexity of caring for this patient population, the military continues to develop and improve TBI diagnostic tools and treatments. Identification of personnel who have sustained a mild TBI is crucial, as is the development of evidence-based guidelines for the management and treatment of mild TBI.

The DoD and VA still face challenges in diagnosing and treating mild TBI, but through continued research and collaboration, they are working towards improving care for those with this condition.

This includes the development of cognitive rehabilitation tools, the implementation of standardized mental status assessment tools, and the expansion of care providers to include non-military personnel.
